

Related Work Map for Anonymous DHT Lookups

A Compact Taxonomy and Where This Series Fits

Unified archive note v0.48 (2026-03-04; archive v154)

Abstract

Anonymous DHT lookups sit at the intersection of query privacy, metadata-hiding transport/scheduling, and deployment discipline. This note is a compact map of the literature to reduce redundancy across the One-True-Archive series. It is not a survey; it is a *reference index*: a minimal taxonomy, a few representative exemplars per branch, and a “what-to-cite-where” map for this archive.

Scope. We organize prior work on DHT lookup privacy (including IPFS/libp2p content routing) into a minimal taxonomy and give a short internal citation map.

Imports. We treat the series’ internal primitives as imported: odds inflation and endpoint sizing (Anonymity A; Synthesis 5), profiler/equalization contracts (Anonymity B), ABOM/OINL (Anonymity C), schedule-only retry wrappers (Operational A), and separation guard objects for primary-path claims (Synthesis 22–23).[8, 9, 10, 12, 13, 14, 15] For the five published math backbones (scheduling, spectral delegation bounds, stop-time padding, and TV/knapsack certificates), this note treats the crosswalk (Synthesis 24) as the canonical pointer and does not re-explain those results.[4]

Exports. Exports (i) a minimal taxonomy, (ii) representative references per branch, and (iii) a compact “what-to-cite-where” table for the rest of the series.

Artifact policy. This archive is source-only; supporting artifacts are available on request as a bundle committed by ABOM/OINL and governed by the series artifact policy (Synthesis 6).[1]

1 A minimal taxonomy

We group work by the *dominant mechanism* used to decouple an initiator from a lookup transcript. Buckets overlap; the point is to keep other papers in this archive from repeatedly re-explaining the same landscape.

1.1 Delegation and random-walk based lookup

The “anonymous lookup” line keeps a structured DHT (e.g., Kademlia[18]) and adds delegation: split queries, cover traffic, and random-walk relaying. Octopus is an archetype: it delegates queries along a random walk and adds mechanisms to resist adversarial nodes.[20, 21] Work analyzing information leaks in structured P2P anonymity systems motivates explicit leakage accounting.[19]

Earlier work also treated the overlay itself as privacy-critical. Salsa and ShadowWalker build anonymity systems around structured overlays and random walks with neighbor verification.[22, 23]

1.2 DHT-backed relay selection and directory distribution (Tor-style low latency)

A closely related line uses DHT lookups not to hide a DHT query, but to scale the *directory/relay selection* service of a low-latency anonymity network. AP3 selects random forwarders via secure lookups; NISAN distributes network information over a DHT to sample relays uniformly; Torsk uses “secret buddy” proxies to perform lookups on behalf of the initiator.[27, 28, 29] These designs motivated follow-on leakage and active-attack analyses and reinforce a core editorial rule of this archive: retry/fallback/state behavior must be treated as first-class adversarial handles, not implementation details.[21, 19, 61]

1.3 Cryptographic query privacy (PIR / OT / PSI)

A second line tries to cryptographically hide query contents/targets. Backes et al. add query privacy to robust DHTs using PIR-style techniques.[31] Peer2PIR explores PIR for IPFS content routing with a different engineering and cost profile.[34]

In this archive, we treat PIR/OT-style approaches as one point on a design frontier. For series-internal baselines situating destination equalization (MC-EQ/CoverSketch) against PIR, delegated routing, and obfuscation/cover approaches, see Release & Destination Paper B.[11]

1.4 Obfuscation, cover distributions, and compatibility-first privacy

Some systems approximate privacy by obfuscating query patterns (decoys, widened prefix fetching, altered termination behavior) while preserving compatibility with existing deployments. Daniel et al. study practical query obfuscation for Kademlia-style lookups.[38] Iris provides privacy-preserving search for authenticated Chord while staying compatible with vanilla Chord nodes.[39]

In this archive, these techniques are treated as instances of a *projection-level contract surface*: identify what is actually observed, define a transcript projection, and export a budgeted equalization claim (Anonymity B; Certified A).[10, 16]

1.5 Deployed mitigations and evolving specs (IPFS / libp2p)

In live systems, lookup privacy is often pursued as incremental deployment hardening: delegated routing endpoints, shared caches, AutoConf-based endpoint discovery, and privacy-relay upgrades (OHTTP). These are not footnotes: they determine *who* can see queries, and they can silently drift the observable surface across time. To keep this note non-redundant, the deployed-surface taxonomy and “what-to-pin” checklist live in Synthesis 30.[5] For measurement context (centralization pressure and request visibility), see Trautwein et al. and Baldur et al.[40, 41]

2 Attacks, measurement, and operational threat surfaces (selected)

Even if the lookup layer is “anonymous,” deployment can re-introduce leakage through retries, downgrade fallbacks, and timing patterns. Classic failure-mode analyses of DHT-based anonymity schemes motivate treating retries and state as first-class adversarial handles.[61, 62]

Operationally, P2P overlay nodes are also recon targets: large-scale scanning and exploitation attempts raise the ambient observation/compromise rate and can interact with “privacy via delegation” assumptions.[67] IPFS deployments face active attacks (e.g., Sybil/eclipse strategies) and censorship pressure that interact with routing privacy.[63, 64, 65, 66]

3 Where this series fits

This archive is not an attempt to out-survey the literature. Its contribution is an *interface discipline*:

- Express privacy in a small number of composable budgets (odds inflation / max-divergence / TV tiers) that propagate to endpoint sizing.[8, 9]
- Identify the few observable features that dominate profiling (e.g., stop-time buckets, committee-contact sets) and turn them into equalization contracts.[10]
- Require that retries, fallbacks, and downgrade surfaces are treated as first-class leakage events (schedule-only wrappers).[13]
- Treat role-separation assumptions for primary paths as explicit guard objects committed by digest (separation manifests).[14]
- Make claims checkable in source-only releases by committing artifacts via ABOM/OINL and notarized receipts.[12, 17]

4 What to cite where (internal map)

Table 2 is a compact “reference index” for readers who ingest the whole series.

5 Limitations

We cite representative exemplars, not every relevant paper. Readers should treat this note as a stable index for the series, not a claim of completeness.

Branch	Representative exemplars (non-exhaustive)
Delegation / random-walk lookups	Octopus; attacks/leak analyses for anonymous lookups; structured-overlay anonymity systems (Salsa, ShadowWalker).[20, 21, 60, 19, 22, 23]
Restricted-route / social-overlay DHT routing	X-Vine (social-link routing + pseudonymity); R ⁵ N (randomized recursive routing for restricted-route overlays); Pisces (random walks over social graphs for decentralized peer discovery); friend-to-friend tunnel discovery and stabilization are the dominant operational issue.[24, 25, 26, 68]
DHT-backed relay selection / directory distribution	AP3; NISAN; Torsk (“secret buddy” proxy lookups); follow-on leak/attack analyses.[27, 28, 29, 21, 19]
Cryptographic query privacy (PIR/OT/PSI)	Adding query privacy to robust DHTs (PIR-style); PIR for IPFS content routing (Peer2PIR), typically protecting query contents but not client network identity without an external anonymity layer.[31, 34]
Obfuscation / protocol-level smoothing	Practical Kademlia query obfuscation (e.g., double hashing, PSI-style obfuscation, prefix fetching); compatibility-first privacy-preserving search in authenticated overlays (Chord).[38, 39]
Deployed mitigations (IPFS/libp2p)	Delegated routing, shared public endpoints/caches, AutoConf endpoint discovery, self-hosted gateway exposure, and OHTTP upgrades. For the deployed-surface taxonomy and “what-to-pin” checklist, see Synthesis 30; for measurement context, see Trautwein et al. and Balduf et al.[5, 40, 41]
Role separation / gateway splits	OHTTP relays and delegated-routing reader-privacy upgrades; standardized discovery/bootstrapping and feature evolution; separation manifests make non-collusion assumptions diffable. Deployed transport/format surfaces (including chunked OHTTP) are treated in Synthesis 30.[56, 57, 14, 5]
Blockchain / Web3 overlays	NC-DHT and related “anonymous DHT” overlays for blockchain routing layers; credentialed membership primitives (e.g., Proof-of-Validator) used to bound Sybil pressure in validator-backed DHTs. [32, 33]

Table 1: A compact taxonomy for lookup privacy work (representative references only).

If you need ...	cite ...
A single-number anonymity budget interpretable by operators	Odds Inflation (Anonymity A) + Endpoint Bridge (Synthesis 5).
A threat-model-specific profiling surface and how to equalize it	Profiling / Equalization Contract (Anonymity B).
How to publish checkable claims without shipping all artifacts	ABOM/OINL (Anonymity C) + Artifact Policy (Synthesis 6).
Why retries/fallbacks must be pinned (and how)	Schedule-Only Retries (Operational A).
Primary-path role separation and non-collusion assumptions	Separation Manifests (Synthesis 22) + Probabilistic Separation Budgets (Synthesis 23) + Worked Example (Synthesis 17).
How to bind an evaluation to a release against grinding	Notarized Certificates (Evaluation 1) + Release Receipts (Release A).

Table 2: A compact “what-to-cite-where” map for the series (to reduce redundancy across papers).
