# EvidenceVault: PACT / OCF: Decision Packages

March 24, 2026

**Abstract**

Portable PACT / OCF evidence in this family is carried by one scoped decision package on one fixed decision scope. That package carries the local decision output, any admission-only residual payload, and one bridge replay slice for the judged decision.

## 1 Decision packages

**Definition 1** (Scoped decision package)**.** *A scoped decision package is the admitted replay-bearing carrier on that fixed decision scope and is the tuple*

$$\mathsf{Pkg} = (\psi, u, \theta, o, a, \Sigma), \qquad \psi = (k, \mathcal{B}),$$

*where $\psi$ is the carried replay-facing role package, with $k \in \{\mathsf{transition}, \mathsf{operational}, \mathsf{admission}\}$ selecting the local decision mode, $u$ is the canonical judged-scope digest of the decision object the package claims to cover, $\theta$ is the carried decision-input context (tools, versions, policies, relevant logs, and comparable scoped environment pins), $o$ is the local decision output (for example ACCEPT, REJECT, or DEFER), $a$ is the optional admission slot, empty when $k \in \{\mathsf{transition}, \mathsf{operational}\}$ and otherwise the inline local tuple*

$$a = (d_{\mathrm{ABOM}}, \Upsilon),$$

*with $d_{\mathrm{ABOM}}$ the signable manifest digest that content-addresses the evaluated artifact(s) and binds them to typed obligations, prerequisites, and evidence references, while $\Upsilon$ records any unsupported deployment-relevant change, compensating-control requirement, debt-limit blocker, authorized override material, rollback / repair marker, or restored discharge condition that policy says still matters for that package reading; and $\Sigma$ is the carried bridge replay slice. The selector $k$ then determines the package-internal case: if $k = \mathsf{transition}$, then $o$ carries the local transition outcome while any before/after artifact pair, step witness, or toolchain justification needed to explain that transition remains carried evidence on $\Sigma$ or carried decision-input context inside $\theta$; if $k = \mathsf{operational}$, then $o$ carries the local operational verdict and $\Sigma$ carries the replayable supporting material behind it; and if $k = \mathsf{admission}$, then the inline slot is present.*
